Using a fast-frame event-related potential (ERP) technique, we recorded the responses of 102 striate cortical neurons to rare (33 to 68 ms), brief (13 to 22 ms) flickering stimuli during the presentation of natural scenes. This resulted in a high (n = 895) multiple-spike per neuron data set, recording ongoing activity across the receptive field of the neuron. Our purpose was to quantify linear and nonlinear responses to this dynamic stimulus environment and to characterize their relations to cortical coding of visual stimuli in the natural environment. We measured responses to the stroboscopic images of a striped object by correlating all spikes in a time window with those in a reference window. This technique, known as the Cross-Correlation technique, revealed a high degree of nonlinearity in some neurons, which increased with stimulus intensity. We also found that responses of a large percentage of neurons were dominated by a transient component, rather than a

Keep your monitor free of dead and stuck pixels by deploying this screensaver. The screensaver will shuffle the pictures on your monitor in a manner that resembles a sliding puzzle. Field of the Invention The present invention relates to a digital signal recording/reproducing device, and more particularly, to a digital signal recording/reproducing device having a function of adjusting a rotational speed of a motor. 2. Description of the Related Art The recording/reproducing device is designed to rotate a spindle motor by being connected to a drive unit. When the spindle motor rotates, recording media and read only memories (ROM) are rotated so that a read/write head is moved to specific locations on the recording media or the ROM to read data recorded in the recording media or the ROM. The spindle motor is connected to a drive unit that uses a motor controller which is normally attached to an IC. The IC is connected to a printed circuit board (PCB) via connectors or connectors. The PCB includes a clock oscillation circuit connected to a power supply, a PLL circuit connected to the clock oscillation circuit, a phase locked loop (PLL) circuit, and a decoder circuit. The decoder circuit is connected to a digital signal detector and a digital signal control. The decoder circuit decodes the digital signal detector and recognizes the rotational speed of the spindle motor. The digital signal detector is connected to a magneto-resistive (MR) head. The MR head is used to read the data from the recording media or the ROM. The rotation of the spindle motor is determined according to a control signal output from the decoder circuit. The digital signal

detector determines whether a recordable amount of data is present on the recording medium or the ROM and when such a recordable amount of data is not present, the digital signal detector does not output the control signal to the decoder circuit. When the recordable amount of data is present on the recording medium, the digital signal detector outputs the control signal. The decoder circuit drives the motor to rotate at a constant speed through the drive unit, and thus b7e8fdf5c8
